In user namespaces, the kernel swaps the kernel address space for the user address space. Once a user space process runs, it resides in a completely separate address space from the kernel. By running a set of user namespaces on the kernel, we can give each user a completely separate address space to run in. This creates a large array of security and isolation benefits for running services in user namespaces. Running a simple shell in a user namespace While the security benefits of user namespaces can be extremely useful, running services in a user namespace can get complicated fast. In this tutorial, we'll walk through running a simple shell in a user namespace. We'll use a slightly more complex scenario than a simple process run in a user namespace, but it provides greater security benefits. We'll set up an LXC container, and once that is running, we'll create a new user namespace. The first step f678ea9f9e
